3 A51 Examples

In this chapter we present a few assembly language programs which use most of the topics discussed in the previous chapters. Before starting to write the first program, we provide a template which explains the general organisation of an 8051 assembly language program. The remarks by the side of the instructions in the template and in the other example programs provide most of the explanations required.

Further examples in C are provided in the Appendix.

3.1 Template.a51

	; Template.a51							
	\$NOMOD51							
<pre>#include <reg52.inc></reg52.inc></pre>			; assuming that we are using an 8032 instead of an 8051					
			; reg52.inc would include all the SFRs present on the 8032					
	start equ 0000H	[; these equates can be changed if using a development					
	1		; board, depending on where the code is to reside.

The first real program, SerP3.a51 is a serial port example program (section 3.2) which basically initializes the UART and then provides routines for reading and writing characters via the UART.

The second program (3.3) is a simple Traffic light controller which also uses the SerP3.a51 routines. It makes use of Timer 2 interrupt which is used to accurately time the duration in seconds for each traffic pattern. Note the way the Interrupt Vector Table (IVT) is jumped over when the program starts executing from location 0000H. For those Interrupts which are not in use, it is generally a good practice to insert a simple RETI instruction at the corresponding IVT location just in case an inadvertent event causes an undesired interrupt to occur.

3.2 Serial Port Example Program

A51 Examples

The second program (section 3.3) is Traffic lights program, and it is targeted to be run from an EPROM. This means that the code area starts from location 0000H. It is also targeted for the FLT-32 development board, which has an 8255 input/output chip added on, providing three additional 8-bit ports, labelled as PORTA, PORTB and PORTC in this program.
